Photo Cell Characteristics

**Applied Science Department
NITTTR, Sector-26, Chandigarh**

EXPERIMENT: To verify inverse square law of radiations using a Photo-electric cell.

APPARATUS: Photo cell (Selenium) mounted in the metal box with connections brought out at terminals, Lamp holder with 60W bulb, Two moving coil analog meters ($1000\mu\text{A}$ & 500mV) mounted on the front panel and connections brought out at terminals, Two single point and two multi points patch cords.

THEORY:

A device used to convert light energy into electrical energy is called Photo Electric Cell. Photocell is based on the phenomenon of Photoelectric effect. Photo cell are of three types.

1. Photo-Emissive Cell.
2. Photo-Voltaic Cell.
3. Photo-Conductive Cell.

Photo-Emissive Cell: There are two types of photo-emissive cells; Vacuum type or gas filled type cells. Generally, it consists of two electrodes i.e. cathode (K) and anode (A). The cathode is in the form of semi-cylindrical plate coated with photo-sensitive material like sodium potassium or cesium i.e. alkali metals. To have large current, it is usually coated with antimony cesium alloy or combination of bismuth, silver, oxygen and cesium. The anode (A) is in the form of a straight wire made of nickel or platinum. The anode (A) faces the cathode (K). These electrodes are sealed in an evacuated glass or quartz bulb according to weather it is to be used with visible or ultra-violet light. As the current due to vacuum is small, so to increase the current, the bulb of the cells is filled with an inert gas like helium, neon, argon etc. at pressure of 1mm of mercury.

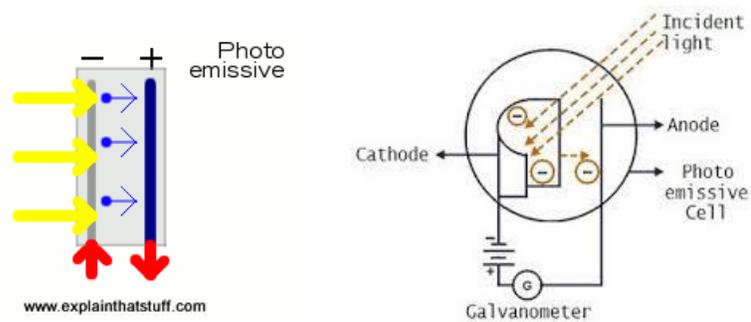

Fig. 1. Schematic and working of photo emissive cell

When photo-electrons flow from cathode to anode, they ionize the gas filled and hence the current gets modified. The main drawback of this type of cell (i.e., gas filled cell) is that the photo-electric current does not vary linearly with the intensity of the light.

Since there is no time lag between the incident light and the flow of electrons and hence current, therefore such a cell is used in television, photometry, fire alarm etc.

Photo-Voltaic Cell:

Photo-Voltaic Cell is based on the principle of inner photo electric cell. This is called true cell because it generates e.m.f. without the application of any external potential difference but by only the light incident on it. It consists of a semi conductor layer formed on the surface of the metal plate by either heat treatment or cathode sputting. A film of semi-transparent metal is coated over the semi-conductor. This film maintains the electrical contact with the semi-conductor and simultaneously allows the incident light to fall on the semi-conductor.

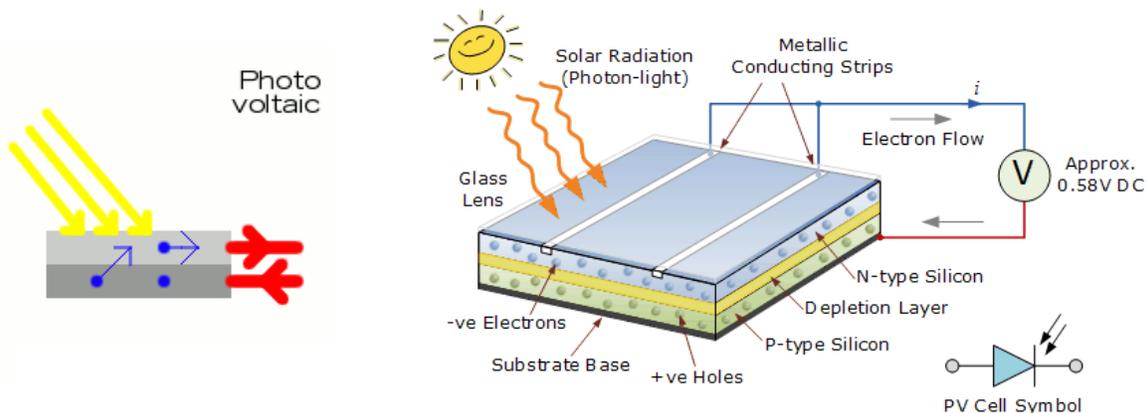

Fig. 2 Schematic and working of photovoltaic cell (Solar cell)

When light is incident on the semi-conductor, electrons are emitted which flow in a direction opposite to the light rays. If the circuit is completed between the surface transparent film and metal base through a low resistance galvanometer (G), the current can be measured. If the resistance of the circuit is very small, the current is proportional to the intensity of incident light. The main advantage of this cell is that it requires no external voltage for its operation. This type of cell is widely used in photographic exposure meters, photometers and illumination meters etc.

Photo-Conductive Cell:

Photo-Conductive Cell is also based on the principle of inner photoelectric effect. It consists of a thin film of semi-conductor like Selenium or Thallium sulphide placed below a thin film of semi-transparent metal. The combination is placed over the block of iron. The iron base and the transparent metal film is connected through battery and resistance. When light falls on the cell, its resistance decreases and hence the current starts flowing in the external circuit.

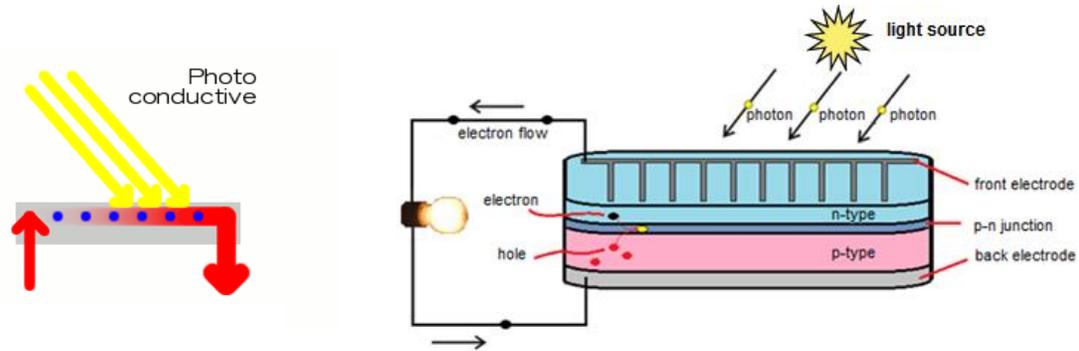

Fig. 3 Schematic and working of Photo conductive cell.

Let 'I' be the luminous intensity of an electric lamp and 'E' be the illuminance at a point distance 'd' from it. According to the inverse square law;

$$E = \frac{I}{d^2}$$

If light from the lamp be incident on the photovoltaic cell placed at a distance 'd' from it, then the photo-current given out is proportional to E and if θ be the corresponding deflection shown by the microammeter then,

$$\theta \propto E$$

or

$$\theta \propto \frac{I}{d^2}$$

or

$$\theta \times d^2 = \text{constant}$$

EXPERIMENTAL CIRCUIT:

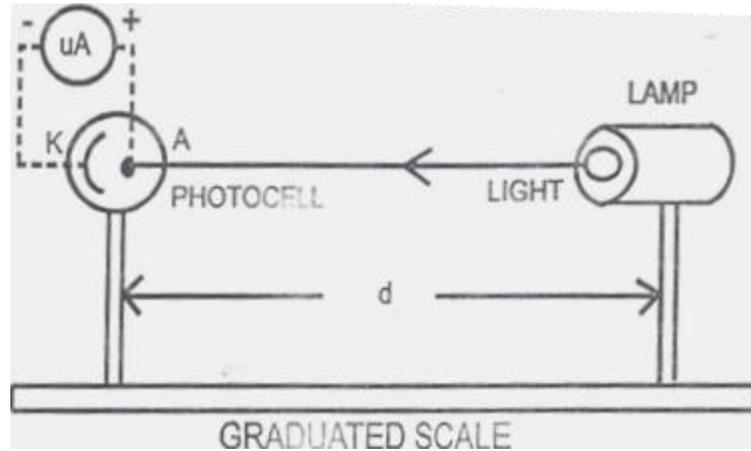

Fig. 4 Experimental Board

PROCEDURE:

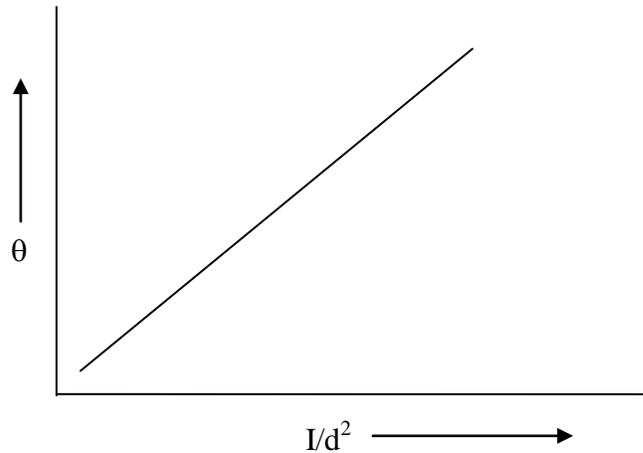

1. The experiment can be performed in the laboratory but it is always good to perform it in a dark room where stray light falling on the photocell can be avoided. In the dark room mount the various parts of the apparatus on the wooden plank provided with a $\frac{1}{2}$ meter scale. Make the other connections as shown in the Fig. 4.
2. Switch on the lamp and adjust it at a suitable distance from the photocell so that the micro ammeter and mill-voltmeter indicate a reasonable deflection.
3. Change the distance of lamp from the voltaic cell and take a series of observations for the corresponding values of distance (d) and deflection (θ).

OBSERVATIONS:

Sr.No.	Position of the lamp	Deflection (θ)	Distance from Photo Cell (d)	$E=I/d^2$
1.				
2.				
3.				
4.				

GRAPH:

Plot a graph between $1/d^2$ and θ , taking $1/d^2$ along X-axis and θ along Y-axis. It should be a straight line.

**PRECAUTIONS:**

1. Stray light should be avoided.
2. The effect of the reflected light from the bench surface should be minimized.
3. Very sensitive micro ammeter should be used.

VIVA VOICE:

- Q.1 What is photoelectric effect?
- Q.2 What is the photo cell?
- Q.3 Define the illuminating power and intensity of illumination.
- Q.4 Which type of the cells is a solar cell?
- Q.5 Give two applications of solar cell in daily life.
